LM5017

100V, 600mA Constant On-Time Synchronous Buck Regulator

General Description

The LM5017 is a 100V, 600mA synchronous step-down regulator with integrated high side and low side MOSFETs. The constant-on-time (COT) control scheme employed in the LM5017 requires no loop compensation, provides excellent transient response, and enables very low step-down ratios. The on-time varies inversely with the input voltage resulting in nearly constant frequency over the input voltage range. A high voltage startup regulator provides bias power for internal operation of the IC and for integrated gate drivers.

A peak current limit circuit protects against overload conditions. The undervoltage lockout (UVLO) circuit allows the input undervoltage threshold and hysteresis to be independently programmed. Other protection features include thermal shutdown and bias supply undervoltage lockout \( V_{CCUVLO} \).

The LM5017 is available in LLP-8 and PSOP-8 plastic packages.

Features

- Wide 9V to 100V Input Range
- Integrated 100V, High and Low Side Switches
- No Schottky Required
- Constant On-time Control
- No Loop Compensation Required
- Ultra-Fast Transient Response
- Nearly Constant Operating Frequency
- Intelligent Peak Current Limit
- Adjustable Output Voltage from 1.225V
- Precision 2% Feedback Reference
- Frequency Adjustable to 1MHz
- Adjustable Undervoltage Lockout (UVLO)
- Remote Shutdown
- Thermal Shutdown

Packages

- LLP-8
- PSOP-8

Applications

- Smart Power Meters
- Telecommunication Systems
- Automotive Electronics
- Isolated Bias Supply

Typical Application

**Note 1:** Absolute Maximum Ratings are limits beyond which damage to the device may occur. Operating Ratings are conditions under which operation of the device is intended to be functional. For guaranteed specifications and test conditions, see the Electrical Characteristics. The RTN pin is the GND reference electrically connected to the substrate.

**Note 2:** For detailed information on soldering plastic PSOP package, refer to the Packaging Data Book available from National Semiconductor Corporation. Max solder time not to exceed 4 seconds.

**Note 3:** All limits are guaranteed by design. All electrical characteristics having room temperature limits are tested during production at $T_A = 25°C$. All hot and cold limits are guaranteed by correlating the electrical characteristics to process and temperature variations and applying statistical process control.

**Note 4:** $V_{CC}$ provides self bias for the internal gate drive and control circuits. Device thermal limitations limit external loading.

**Note 5:** The human body model is a 100pF capacitor discharged through a 1.5kΩ resistor into each pin.

FIGURE 2. Functional Block Diagram
**Functional Description**

The LM5017 step-down switching regulator features all the functions needed to implement a low cost, efficient, buck converter capable of supplying up to 0.6A to the load. This high voltage regulator contains 100V, N-channel buck and synchronous switches, is easy to implement, and is provided in thermally enhanced PSOP-8 and LLP-8 packages. The regulator operation is based on a constant on-time control scheme using an on-time inversely proportional to \( V_{IN} \). This control scheme does not require loop compensation. The current limit is implemented with a forced off-time inversely proportional to \( V_{OUT} \). This scheme ensures short circuit protection while providing minimum foldback. The simplified block diagram of the LM5017 is shown in Figure 2, Functional Block Diagram.

The LM5017 can be applied in numerous applications to efficiently regulate down higher voltages. This regulator is well suited for 48V telecom and 42V automotive power bus ranges. Protection features include: thermal shutdown, Undervoltage Lockout (UVLO), minimum forced off-time, and an intelligent current limit.

**Control Overview**

The LM5017 buck regulator employs a control principle based on a comparator and a one-shot on-timer, with the output voltage feedback (FB) compared to an internal reference (1.225V). If the FB voltage is below the reference the internal buck switch is turned on for the one-shot timer period, which is a function of the input voltage and the programming resistor (\( R_{ON} \)). Following the on-time the switch remains off until the FB voltage falls below the reference, but never before the minimum off-time forced by the minimum off-time one-shot timer. When the FB pin voltage falls below the reference and the minimum off-time one-shot period expires, the buck switch is turned on for another on-time one-shot period. This will continue until regulation is achieved and the FB voltage is approximately equal to 1.225V (typ).

In a synchronous buck converter, the low side (sync) FET is 'on' when the high side (buck) FET is 'off'. The inductor current ramps up when the high side switch is 'on' and ramps down when the high side switch is 'off'. There is no diode emulation feature in this IC, and therefore, the inductor current may ramp in the negative direction at light load. This causes the converter to operate in continuous conduction mode (CCM) regardless of the output loading. The operating frequency remains relatively constant with load and line variations. The operating frequency can be calculated as follows:

\[
 f_{sw} = \frac{V_{OUT}}{10^{10} \times R_{ON}}
\]

The output voltage (\( V_{OUT} \)) is set by two external resistors (\( R_{FB1}, R_{FB2} \)). The regulated output voltage is calculated as follows:

\[
 V_{OUT} = 1.225V \times \frac{R_{FB2} + R_{FB1}}{R_{FB1}}
\]

\[
 \frac{R_{FB2}}{R_{FB1}} = \frac{V_{OUT} - 1.225V}{1.225V}
\]

This regulator regulates the output voltage based on ripple voltage at the feedback input, requiring a minimum amount of ESR for the output capacitor (\( C_{OUT} \)). A minimum of 25mV of ripple voltage at the feedback pin (FB) is required for the LM5017. In cases where the capacitor ESR is too small, additional series resistance may be required (\( R_C \) in Figure 3 Low Ripple Output Configuration).

For applications where lower output ripple is required the output can be taken directly from a low ESR output capacitor, as shown in Figure 3 Low Ripple Output Configuration. However, \( R_C \) slightly degrades the load regulation.

**V_{CC} Regulator**

The LM5017 contains an internal high voltage linear regulator with a nominal output of 7.6V. The input pin (\( V_{IN} \)) can be connected directly to the line voltages up to 100V. The \( V_{CC} \) regulator is internally current limited to 30mA. The regulator sources current into the external capacitor at \( V_{CC} \). This regulator supplies current to internal circuit blocks including the synchronous MOSFET driver and the logic circuits. When the voltage on the \( V_{CC} \) pin reaches the undervoltage lockout (\( V_{CC} \) UVLO) threshold of 4.5V, the IC is enabled.

The \( V_{CC} \) regulator contains an internal diode connection to the BST pin to replenish the charge in the gate drive boot capacitor when SW pin is low.

At high input voltages, the power dissipated in the high voltage regulator is significant and can limit the overall achievable output power. As an example, with the input at 48V and switching at high frequency, the \( V_{CC} \) regulator may supply up to 7mA of current resulting in 48V x 7mA = 336mW of power dissipation. If the \( V_{CC} \) voltage is driven externally by an alternate voltage source, between 8V and 13V, the internal regulator is disabled. This reduces the power dissipation in the IC.

---

**FIGURE 2. Functional Block Diagram**

**FIGURE 3. Low Ripple Output Configuration**

www.ti.com
Regulation Comparator
The feedback voltage at FB is compared to an internal 1.225V reference. In normal operation, when the output voltage is in regulation, an on-time period is initiated when the voltage at FB falls below 1.225V. The high side switch will stay on for the on-time, causing the FB voltage to rise above 1.225V. After the on-time period, the high side switch will stay off until the FB voltage again falls below 1.225V. During start-up, the FB voltage will be below 1.225V at the end of each on-time, causing the high side switch to turn on immediately after the minimum forced off-time of 144ns. The high side switch can be turned off before the on-time is over, if the peak current in the inductor reaches the current limit threshold.

Overvoltage Comparator
The feedback voltage at FB is compared to an internal 1.62V reference. If the voltage at FB rises above 1.62V the on-time pulse is immediately terminated. This condition can occur if the input voltage and/or the output load changes suddenly. The high side switch will not turn on again until the voltage at FB falls below 1.225V.

On-Time Generator
The on-time for the LM5017 is determined by the RON resistor, and is inversely proportional to the input voltage (Vin), resulting in a nearly constant frequency as Vin is varied over its range. The on-time equation for the LM5017 is:

\[ T_{ON} = \frac{10^{10} \times R_{ON}}{V_{IN}} \]

See figure “TON vs VIN and RON” in the section “Performance Curves”. RON should be selected for a minimum on-time (at maximum VIN) greater than 100ns, for proper operation. This requirement limits the maximum switching frequency for high VIN.

Current Limit
The LM5017 contains an intelligent current limit off-timer. If the current in the buck switch exceeds 0.02A the present cycle is immediately terminated, and a non-resetable off-timer is initiated. The length of off-time is controlled by the FB voltage and the input voltage Vin. As an example, when FB = 0V and VIN = 48V, the maximum off-time is set to 16μs. This condition occurs when the output is shorted, and during the initial part of start-up. This amount of time ensures safe short circuit operation up to the maximum input voltage of 100V.

In cases of overload where the FB voltage is above zero volts (not a short circuit) the current limit off-time is reduced. Reducing the off-time during less severe overloads reduces the amount of foldback, recovery time, and start-up time. The off-time is calculated from the following equation:

\[ T_{OFF(LIMIT)} = \frac{0.07 \times V_{IN}}{V_{FB} + 0.2V} \mu s \]

The current limit protection feature is peak limited. The maximum average output will be less than the peak.

N-Channel Buck Switch and Driver
The LM5017 integrates an N-Channel Buck switch and associated floating high voltage gate driver. The gate driver circuit works in conjunction with an external bootstrap capacitor and an internal high voltage diode. A 0.01μF ceramic capacitor connected between the BST pin and the SW pin provides the voltage to the driver during the on-time. During each off-time, the SW pin is at approximately 0V, and the bootstrap capacitor charges from VCC through the internal diode. The minimum off-timer, set to 144ns, ensures a minimum time each cycle to recharge the bootstrap capacitor.

Synchronous Rectifier
The LM5017 provides an internal synchronous N-Channel MOSFET rectifier. This MOSFET provides a path for the inductor current to flow when the high-side MOSFET is turned off.

The synchronous rectifier has no diode emulation mode, and is designed to keep the regulator in continuous conduction mode even during light loads which would otherwise result in discontinuous operation.

Undervoltage Detector
The LM5017 contains a dual level undervoltage lockout (UVLO) circuit. When the UVLO pin voltage is below 0.66V, the controller is in a low current shutdown mode. When the UVLO pin voltage is greater than 0.66V but less than 1.225V, the controller is in standby mode. In standby mode the VCC bias regulator is active while the regulator output is disabled. When the VCC pin exceeds the UVCC undervoltage threshold and the UVLO pin voltage is greater than 1.225V, normal operation begins. An external set-point voltage divider from VIN to GND can be used to set the minimum operating voltage of the regulator.

UVLO hysteresis is accomplished with an internal 20μA current source that is switched on or off into the impedance of the set-point divider. When the UVLO threshold is exceeded, the current source is activated to quickly raise the voltage at the UVLO pin. The hysteresis is equal to the value of this current times the resistance RUV2.

</tbody>
</table>

If the UVLO pin is wired directly to the VIN pin, the regulator will begin operation once the VCC undervoltage is satisfied.
Thermal Protection
The LM5017 should be operated so the junction temperature does not exceed 150°C during normal operation. An internal Thermal Shutdown circuit is provided to protect the LM5017 in the event of a higher than normal junction temperature. When activated, typically at 165°C, the controller is forced into a low power reset state, disabling the buck switch and the $V_{CC}$ regulator. This feature prevents catastrophic failures from accidental device overheating. When the junction temperature reduces below 145°C (typical hysteresis = 20°C), the $V_{CC}$ regulator is enabled, and normal operation is resumed.
Application Information

SELECTION OF EXTERNAL COMPONENTS

Selection of external components is illustrated through a design example. The design example specifications are as follows:

<table>
<thead>
<tr>
<th>Buck Converter Design Specifications</th>
</tr>
</thead>
<tbody>
<tr>
<td>Input voltage range</td>
</tr>
<tr>
<td>Output voltage</td>
</tr>
<tr>
<td>Maximum Load current</td>
</tr>
<tr>
<td>Switching Frequency</td>
</tr>
</tbody>
</table>

RFB1, RFB2:

\[ V_{\text{OUT}} = V_{\text{FB}} \times \left( \frac{R_{\text{FB2}}}{R_{\text{FB1}}} + 1 \right), \]

and since \( V_{\text{FB}} = 1.225V \), the ratio of \( R_{\text{FB2}} \) to \( R_{\text{FB1}} \) calculates as 7:1. Standard values of 6.98kΩ and 1.00kΩ are chosen. Other values could be used as long as the 7:1 ratio is maintained.

Frequency Selection:

At the minimum input voltage, the maximum switching frequency of LM5017 is restricted by the forced minimum off-time \( (T_{\text{OFF(MIN)}}) \) as given by:

\[ f_{\text{SW(MAX)}} = \frac{1 - D_{\text{MAX}}}{T_{\text{OFF(MIN)}}} = \frac{1 - 10/12.5}{200 \text{ ns}} = 1 \text{ MHz} \]

Similarly, at maximum input voltage, the maximum switching frequency of LM5017 is restricted by the minimum \( T_{\text{ON}} \) as given by:

\[ f_{\text{SW(MAX)}} = \frac{D_{\text{MIN}}}{T_{\text{ON(MIN)}}} = \frac{10/95}{100 \text{ ns}} = 1.05 \text{ MHz} \]

Resistor \( R_{\text{ON}} \) sets the nominal switching frequency based on the following equations:

\[ f_{\text{SW}} = \frac{V_{\text{OUT}}}{K \times R_{\text{ON}}} \]

where \( K = 1 \times 10^{-10} \). Operation at high switching frequency results in lower efficiency while providing the smallest solution. For this example a conservative 200kHz was selected, resulting in \( R_{\text{ON}} = 504k\Omega \). Selecting a standard value for \( R_{\text{ON}} = 499k\Omega \) results in a nominal frequency of 202kHz.

Inductor Selection:

The minimum inductance is selected to limit the output ripple to 20 to 40 percent of the maximum load current. In addition, the peak inductor current at maximum load should be smaller than the minimum current limit as given in electrical characteristics table. The inductor current ripple is given by:

\[ \Delta I_{\text{L}} = \frac{V_{\text{IN}} - V_{\text{OUT}}}{L_{\text{I}}} \times f_{\text{SW}} \times \frac{V_{\text{OUT}}}{V_{\text{IN}}} \]

The maximum ripple is observed at maximum input voltage. Substituting \( V_{\text{IN}} = 95V \) and \( \Delta I_{\text{L}} = 40 \text{ percent} \times I_{\text{OUT(max)}} \) results in \( L_{\text{I}} = 198.4\mu\text{H} \). The next higher standard value of 220μH is chosen. The peak-to-peak minimum and maximum inductor current ripples of 35mA and 204mA are given at minimum and maximum input voltages respectively. The peak inductor and switch current is given by

\[ I_{\text{L}(\text{peak})} = I_{\text{OUT}} + \frac{\Delta I_{\text{L(max)}}}{2} = 602 \text{ mA} \]

which is smaller than the minimum current limit. The inductor should be able to withstand the maximum current limit of 1.3A, which can be reached during startup and overload conditions.

FIGURE 5. Reference Schematic for Selection of External Components
Output Capacitor:
The output capacitor is selected to minimize the capacitive ripple across it. The maximum ripple is observed at maximum input voltage and is given by:

\[ C_{OUT} = \frac{\Delta I_{L}}{8 \times f_{SW} \times \Delta V_{ripple}} \]

where \( \Delta V_{ripple} \) is the voltage ripple across the capacitor. Substituting \( \Delta V_{ripple} = 10\text{mV} \) gives \( C_{OUT} = 12.64\mu\text{F} \). A 22\( \mu\text{F} \) standard value is selected. An X5R or X7R type capacitor with a voltage rating 16V or higher should be selected.

Series Ripple Resistor \( R_C \):
The series resistor should be selected to produce sufficient ripple at the feedback node. The ripple produced by \( R_C \) is proportional to the inductor current ripple, and therefore \( R_C \) should be chosen for minimum inductor current ripple which occurs at minimum input voltage. The \( R_C \) is calculated by the equation:

\[ R_C \geq \frac{25 \text{mV}}{\Delta I_{L(MIN)} \times V_{OUT}} \times V_{REF} \]

This gives an \( R_C \) of greater than or equal to 5.15\( \Omega \). Selecting \( R_C = 5.23\Omega \) results in ~1V of maximum output voltage ripple. For applications requiring lower output voltage ripple, Type II or Type III ripple injection circuits should be used as described in the section “Ripple Configuration”.

\( V_{CC} \) and Bootstrap Capacitor:
The \( V_{CC} \) capacitor provides charge to bootstrap capacitor as well as internal circuitry and low side gate driver. The Bootstrap capacitor provides charge to high side gate driver. A good value for \( CV_{CC} \) is 1\( \mu\text{F} \). A good value for \( C_{BST} \) is 0.01\( \mu\text{F} \).

Input Capacitor:
Input capacitor should be large enough to limit the input voltage ripple:

\[ C_{IN} \geq \frac{I_{OUT(MAX)}}{8 \times f_{SW} \times \Delta V_{IN}} \]

choosing a \( \Delta V_{IN} = 0.5\text{V} \) gives a minimum \( C_{IN} = 1.24\mu\text{F} \). A standard value of 2.2\( \mu\text{F} \) is selected. The input capacitor should be rated for the maximum input voltage under all conditions. A 100V, X7R dielectric should be selected for this design.

Input capacitor should be placed directly across \( V_{IN} \) and \( RTN \) (pin 2 and 1) of the IC. If it is not possible to place all of the input capacitor close to the IC, a 0.47\( \mu\text{F} \) capacitor should be placed near the IC to provide a bypass path for the high frequency component of the switching current. This helps limit the switching noise.

UVLO Resistors:
The UVLO resistors \( R_{FB1} \) and \( R_{FB2} \) set the UVLO threshold and hysteresis according to the following relationship:

\[ V_{IN(HYS)} = I_{HYS} \times R_{UV2} \]

and

\[ V_{IN(UVLO, rising)} = 1.225V \times \left( \frac{R_{UV2}}{R_{UV1}} + 1 \right) \]

where \( I_{HYS} = 20\mu\text{A} \). Setting UVLO hysteresis of 2.5V and UVLO rising threshold of 12V results in \( R_{UV1} = 14.53k\Omega \) and \( R_{UV2} = 125k\Omega \). Selecting standard value of \( R_{UV1} = 14k\Omega \) and \( R_{UV2} = 125k\Omega \) results in UVLO thresholds and hysteresis of 12.4V and 2.5V respectively.
APPLICATION CIRCUIT: 12V TO 95V INPUT AND 10V, 500mA OUTPUT BUCK CONVERTER

The application schematic of a buck supply is shown in Figure 6 below. For output voltage \( V_{\text{OUT}} \) above the maximum regulation threshold of \( V_{\text{CC}} \) (8.55V, see electrical characteristics), the \( V_{\text{CC}} \) pin can be connected to \( V_{\text{OUT}} \) through a diode (D2), as shown below, for higher efficiency and lower power dissipation in the IC.

![Figure 6. Final Schematic for 12V to 95V Input, and 10V, 500mA Output Buck Converter](image)

ISOLATED DC-DC CONVERTER USING LM5017

An isolated supply using LM5017 is shown in Figure 7 below. Inductor \( L \) in a typical buck circuit is replaced with a coupled inductor \( X_1 \). A diode \( D_1 \) is used to rectify the voltage on a secondary output. The nominal voltage at the secondary output \( V_{\text{OUT2}} \) is given by:

\[
V_{\text{OUT2}} = V_{\text{OUT1}} \times \frac{N_S}{N_P} - V_F
\]

where \( V_F \) is the forward voltage drop of \( D_1 \), and \( N_P, N_S \) are the number of turns on the primary and secondary of coupled inductor \( X_1 \). For output voltage \( V_{\text{OUT1}} \) above the maximum \( V_{\text{CC}} \) (8.55V), the \( V_{\text{CC}} \) pin can be diode connected to \( V_{\text{OUT1}} \) for higher efficiency and low dissipation in the IC. See AN-2204 for a complete isolated bias design with LM5017.

![Figure 7. Typical Isolated Application Schematic](image)

RIPPLE CONFIGURATION

LM5017 uses Constant-On-Time (COT) control scheme, in which the on-time is terminated by an on-timer, and the off-time is terminated by the feedback voltage \( V_{FB} \) falling below the reference voltage \( V_{\text{REF}} \). Therefore, for stable operation, the feedback voltage must decrease monotonically, in phase with the inductor current during the off-time. Furthermore, this change in feedback voltage \( V_{FB} \) during off-time must be large enough to suppress any noise component present at the feedback node.

Table 1 shows three different methods for generating appropriate voltage ripple at the feedback node. Type 1 and Type 2 ripple circuits couple the ripple at the output of the converter to the feedback node \( (FB) \). The output voltage ripple has two components:

1. Capacitive ripple caused by the inductor current ripple charging/discharging the output capacitor.
2. Resistive ripple caused by the inductor current ripple flowing through the ESR of the output capacitor.
The capacitive ripple is not in phase with the inductor current. As a result, the capacitive ripple does not decrease monotonically during the off-time. The resistive ripple is in phase with the inductor current and decreases monotonically during the off-time. The resistive ripple must exceed the capacitive ripple at the output node \( V_{\text{OUT}} \) for stable operation. If this condition is not satisfied unstable switching behavior is observed in COT converters, with multiple on-time bursts in close succession followed by a long off-time.

Type 3 ripple method uses \( R_r \) and \( C_r \) and the switch node (SW) voltage to generate a triangular ramp. This triangular ramp is ac coupled using \( C_{ac} \) to the feedback node (FB). Since this circuit does not use the output voltage ripple, it is ideally suited for applications where low output voltage ripple is required. See application note AN-1481 for more details for each ripple generation method.

### SOFT START

A soft-start feature can be implemented to the LM5017 using an external circuit. As shown in Figure 8, the soft-start circuit consists of one capacitor, \( C_1 \), two resistors, \( R_1 \) and \( R_2 \), and a diode, D. During the initial start-up, the VCC voltage is established prior to the \( V_{\text{OUT}} \) voltage. D is thereby forward biased and the FB voltage is pulled up above the reference voltage (1.225V). The switcher is disabled. With the charging of the capacitor \( C_1 \), the voltage at node B gradually decreases. Due to the action of the control circuit, \( V_{\text{OUT}} \) will gradually rise to maintain the FB voltage at the reference voltage. Once the voltage at node B is lower than the FB voltage, plus the voltage drop of D, the soft-start is finished and D is reverse biased.

During the initial part of the start-up, the FB voltage can be approximated as follows. Please note that the effect of \( R_1 \) has been ignored to simplify the calculation:

\[
V_{FB} = (VCC - V_D) \times \frac{R_{FB1} \times R_{FB2}}{R_2 \times (R_{FB1} + R_{FB2}) + R_{FB1} \times R_{FB2}}
\]

To achieve the desired soft-start, the following design guidance is recommended:

1. \( R_2 \) is selected so that \( V_{FB} \) is higher than 1.225V for a \( V_{CC} \) of 4.5V, but is lower than 5V when \( V_{CC} \) is 8.55V. If an external \( V_{CC} \) is used, \( V_{FB} \) should not exceed 5V at maximum \( V_{CC} \).
2. \( C_1 \) is selected to achieve the desired start-up time that can be determined as follows:

\[
C_1 = \frac{3300 \, \text{pF}}{100 \, \text{nF}}
\]

(3) \( R_1 \) is used to maintain the node B voltage at zero after the soft-start is finished. A value larger than the feedback resistor divider is preferred.

Based on the schematic shown in Figure 6, selecting \( C_1=1\,\mu\text{F} \), \( R_2=1\,\text{k} \), \( R_1=30\,\text{k} \) results in a soft-start time of about 2ms.

![FIGURE 8. Soft-Start Circuit](www.ti.com)
LAYOUT RECOMMENDATION
A proper layout is essential for optimum performance of the circuit. In particular, the following guidelines should be observed:

1. **C<sub>IN</sub>**: The loop consisting of input capacitor (C<sub>IN</sub>), V<sub>IN</sub> pin, and RTN pin carries switching currents. Therefore, the input capacitor should be placed close to the IC, directly across V<sub>IN</sub> and RTN pins and the connections to these two pins should be direct to minimize the loop area. In general it is not possible to accommodate all of input capacitance near the IC. A good practice is to use a 0.1μF or 0.47μF capacitor directly across the V<sub>IN</sub> and RTN pins close to the IC, and the remaining bulk capacitor as close as possible (Refer to Figure 9 Placement of Bypass Capacitors).

2. **C<sub>VCC</sub>** and **C<sub>BST</sub>**: The V<sub>CC</sub> and bootstrap (BST) bypass capacitors supply switching currents to the high and low side gate drivers. These two capacitors should also be placed as close to the IC as possible, and the connecting trace length and loop area should be minimized (See Figure 9 Placement of Bypass Capacitors).

3. The **Feedback trace** carries the output voltage information and a small ripple component that is necessary for proper operation of LM5017. Therefore, care should be taken while routing the feedback trace to avoid coupling any noise to this pin. In particular, feedback trace should not run close to magnetic components, or parallel to any other switching trace.

4. **SW trace**: The SW node switches rapidly between V<sub>IN</sub> and GND every cycle and is therefore a possible source of noise. The SW node area should be minimized. In particular, the SW node should not be inadvertently connected to a copper plane or pour.
